

Lab 4: Overlay Network and VXLAN

What is Overlay Network?

An overlay network can be thought of as a computer network on top of another network. All nodes in an overlay network are connected with one another by means of logical or virtual links and each of these links correspond to a path in the underlying network. You can refer to the following links for more details.

<https://www.juniper.net/documentation/us/en/software/junos/evpn-vxlan/topics/topic-map/sdn-vxlan.html>

Experiment with VXLAN

We need two virtual machines for this VXLAN experiment. In each VM, we use Mininet to set up a LAN with 2 hosts and 1 OVS switch. Note that both LANs in the two VMs are behind NAT. Hence, h1/h2 cannot communicate with h3/h4. The purpose of this lab is to use VXLAN to build a tunnel or an overlay network between these two LANs, so that h1-h4 can directly communicate.

First, we will use the two VMs created at lab1.

IP address on VM1:

enp0s8: 192.168.56.101.

IP address on VM2:

enp0s8: 192.168.56.102.

Figure 1

Please construct the network topology in figure 1 using mininet on VM1 and VM2. (Set all the links bandwidth as 10Mbps, the packet loss rate as 0%, and the time delay as 5ms).

Set the IP addresses of hosts and switches as follows,

On VM 1:

In mininet, set the IPs for both hosts:

h1 ifconfig h1-eth0 10.0.0.1 netmask 255.0.0.0

h2 ifconfig h2-eth0 10.0.0.2 netmask 255.0.0.0

Open another terminal, set the switch IP:

```
sudo ifconfig s1 10.0.0.111/8 up
```

On VM 2:

In mininet, set the IPs for both hosts:

```
h3 ifconfig h3-eth0 10.0.0.3 netmask 255.0.0.0
```

```
h4 ifconfig h4-eth0 10.0.0.4 netmask 255.0.0.0
```

Open another terminal, set the switch IP:

```
sudo ifconfig s2 10.0.0.112/8 up
```

Now, if you ping 10.0.0.112/10.0.0.3/10.0.0.4 from 10.0.0.111/10.0.0.1/10.0.0.2, there will be no response.

Then, we will use VXLAN to build a tunnel, through which h1-h4 can directly communicate.

Step 1:

On VM1:

```
sudo ovs-vsctl add-br br1
```

Assign the IP of enp0s8 to br1:

```
sudo ovs-vsctl add-port br1 enp0s8
```

```
sudo ifconfig br1 192.168.56.101/24 up
```

Add a new default route for br1:

```
sudo route add default gw 192.168.56.201
```

On VM2:

```
sudo ovs-vsctl add-br br1
```

Assign the IP of enp0s8 to br1:

```
sudo ovs-vsctl add-port br1 enp0s8
```

```
sudo ifconfig br1 192.168.56.102/24 up
```

Add a new default route for br1:

```
sudo route add default gw 192.168.56.201
```

Step 2:

On VM1:

```
sudo ovs-vsctl add-port s1 vxlan0 -- set interface vxlan0 type=vxlan  
options:remote_ip=192.168.56.102
```

On VM2:

```
sudo ovs-vsctl add-port s2 vxlan0 -- set interface vxlan0 type=vxlan  
options:remote_ip=192.168.56.101
```

Now, you can ping 10.0.0.112/10.0.0.3/10.0.0.4 from 10.0.0.111/10.0.0.1/10.0.0.2.

Homework:

1. (30 points) Ping 10.0.0.111 from 10.0.0.112 (in your terminal of VM2) and use Wireshark to monitor the interfaces s2 and enp0s8, and describe the protocols used in this procedure and your findings.

Requirements:

Please provide the screenshot of the wireshark interface in your report. Your description and findings should align with the information in wireshark interface.

2. (50 points) Use iperf to test the network bandwidth between the two virtual machines

- Test the bandwidth between 192.168.56.101 and 192.168.56.102
- Test the bandwidth between 10.0.0.1/10.0.0.2/10.0.0.111 and 10.0.0.3

Compare the above results and explain the reason. (Hint: you may need to specify a reasonable MTU size in order for your iperf to work in this case. Please also think about why.)

Requirements:

Please provide the screenshot of your terminals in your report.

3. (20 points) Similar to Q2, use ping to test the network latency and analyze your results.

Requirements:

Please provide the screenshot of your terminals in your report.
